

# Willard Spur: Nutrients and Ecosystem Processes

# Biogeochemical Patterns and Processes

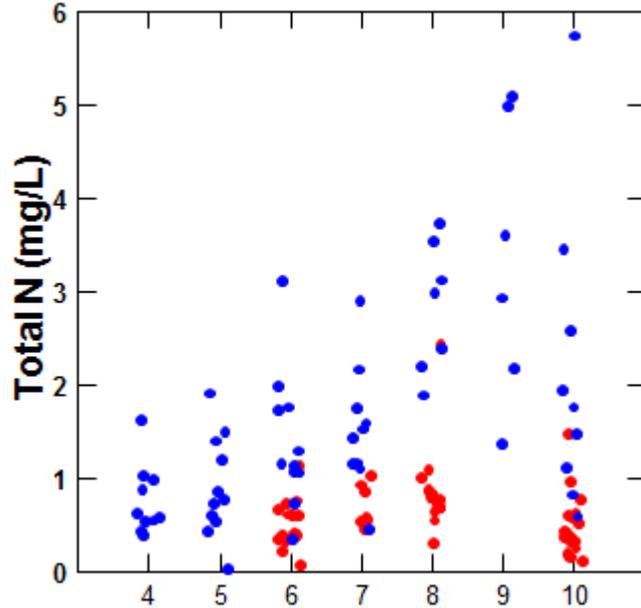

# Water Column Nutrient Pools

## Total Nutrient Pools

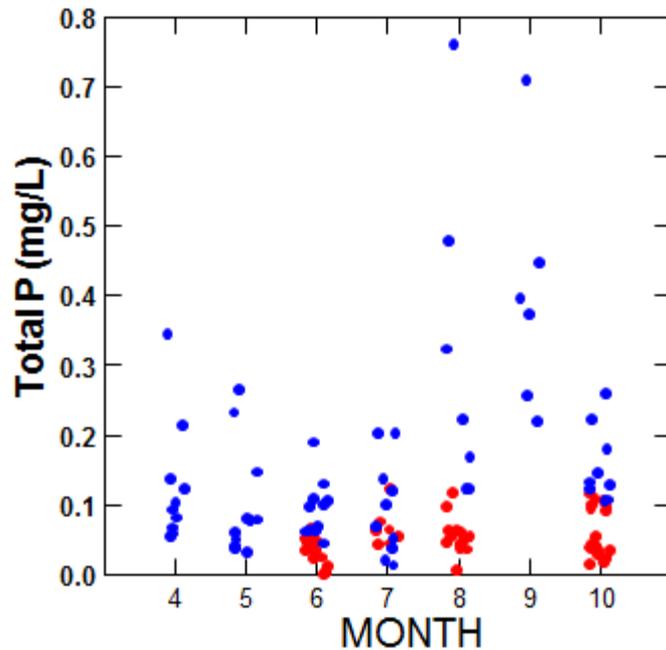

- Total N (TKN + NO<sub>3</sub>) concentrations greater in 2012 vs. 2011 -- Across Open Water sites
- Total P concentrations *occasionally* greater in 2012 vs 2011 -- Particularly sites near Inflows
- **Western-most sites had lowest TN and TP concentrations**

# Water Column Nutrient Pools

## TN

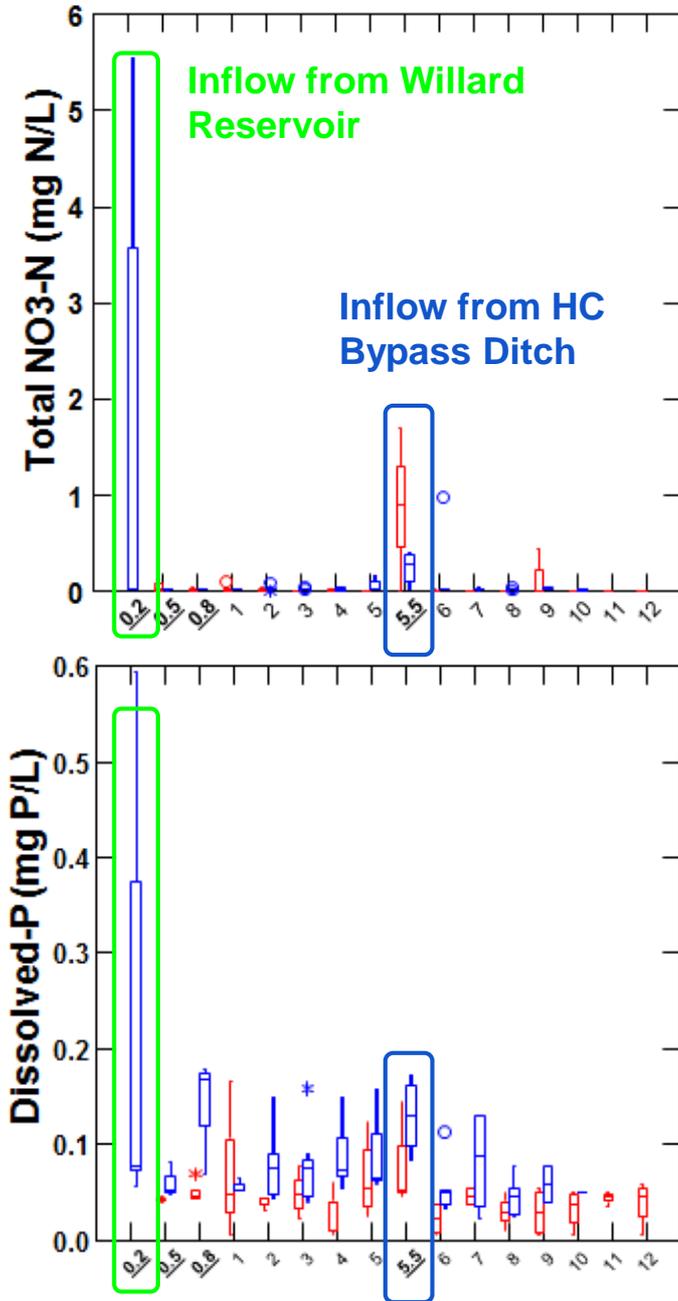

- Increased over time in 2012, not 2011
  - Flushing?
- Highest TN concentrations in late summer
- 90%ile:
  - 2011 = 0.88 mg N/L
  - 2012 = 3.18 mg N/L

## TP

- Increased over time in 2012, not 2011
- 90%ile:
  - 2011 = 0.098 mg P/L
  - 2012 = 0.333 mg P/L

### 3. Water Column Dissolved Nutrient Pools

- Inorganic N and P pools are generally low
  - Except for sites near inflows
- Given the seasonal increases in TN and TP, this suggests that:
  - Inorganic nutrient cycling is tight (ie that available nutrients are rapidly taken up)
  - ***Nutrient fluxes from inflows are rapidly assimilated within the Open Water sites***

# Metabolism: The Carbon Story

Scale experimental processing rates to the Willard Spur ecosystem

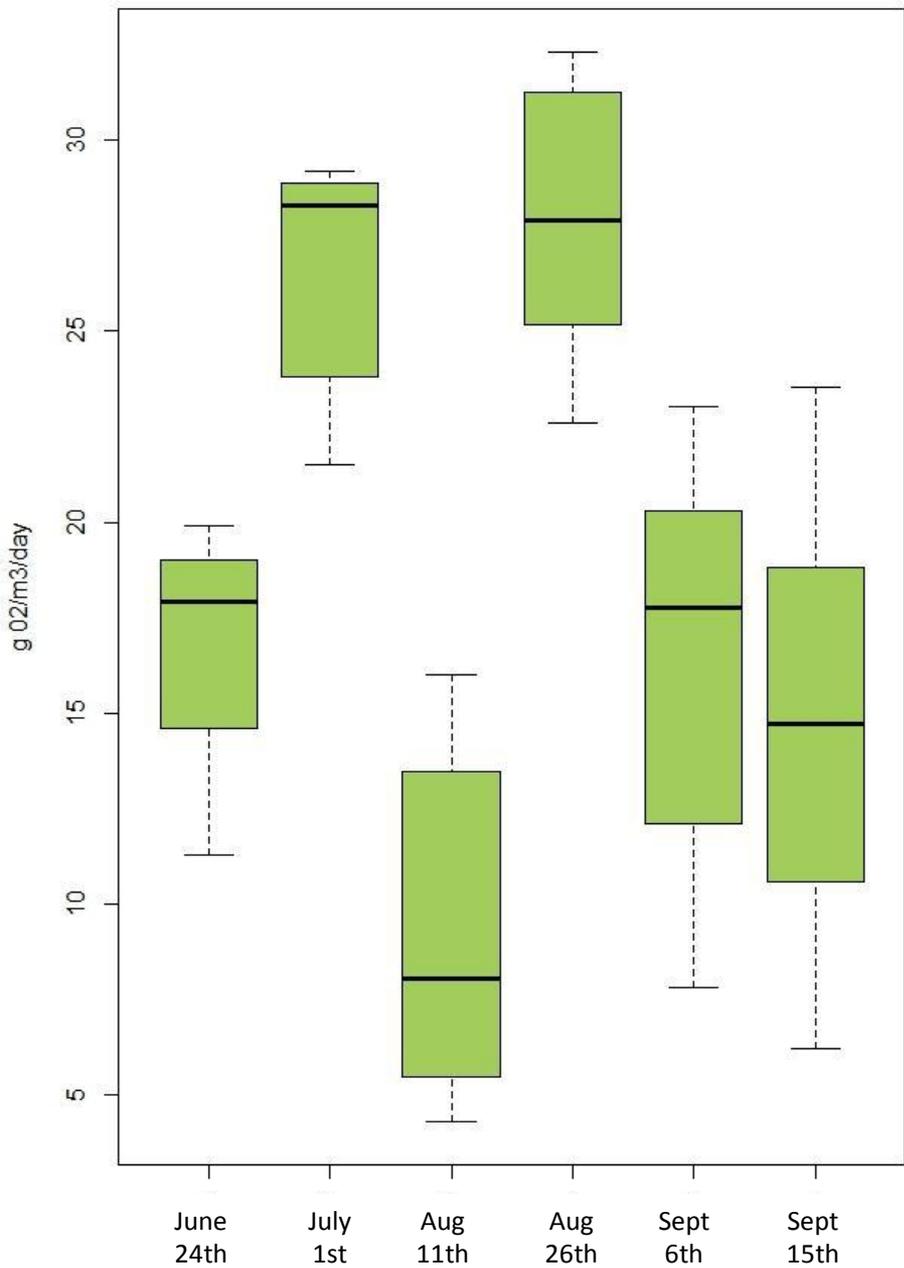

## Primary Production

- Links rates of C production to measures of O<sub>2</sub> production
- Daytime O<sub>2</sub> = GPP + reaeration
- Potential to provide linkages between discrete measurements
- Rates dictated by daytime conditions (production requires photosynthesis)
- May be particularly important in dynamic ecosystems

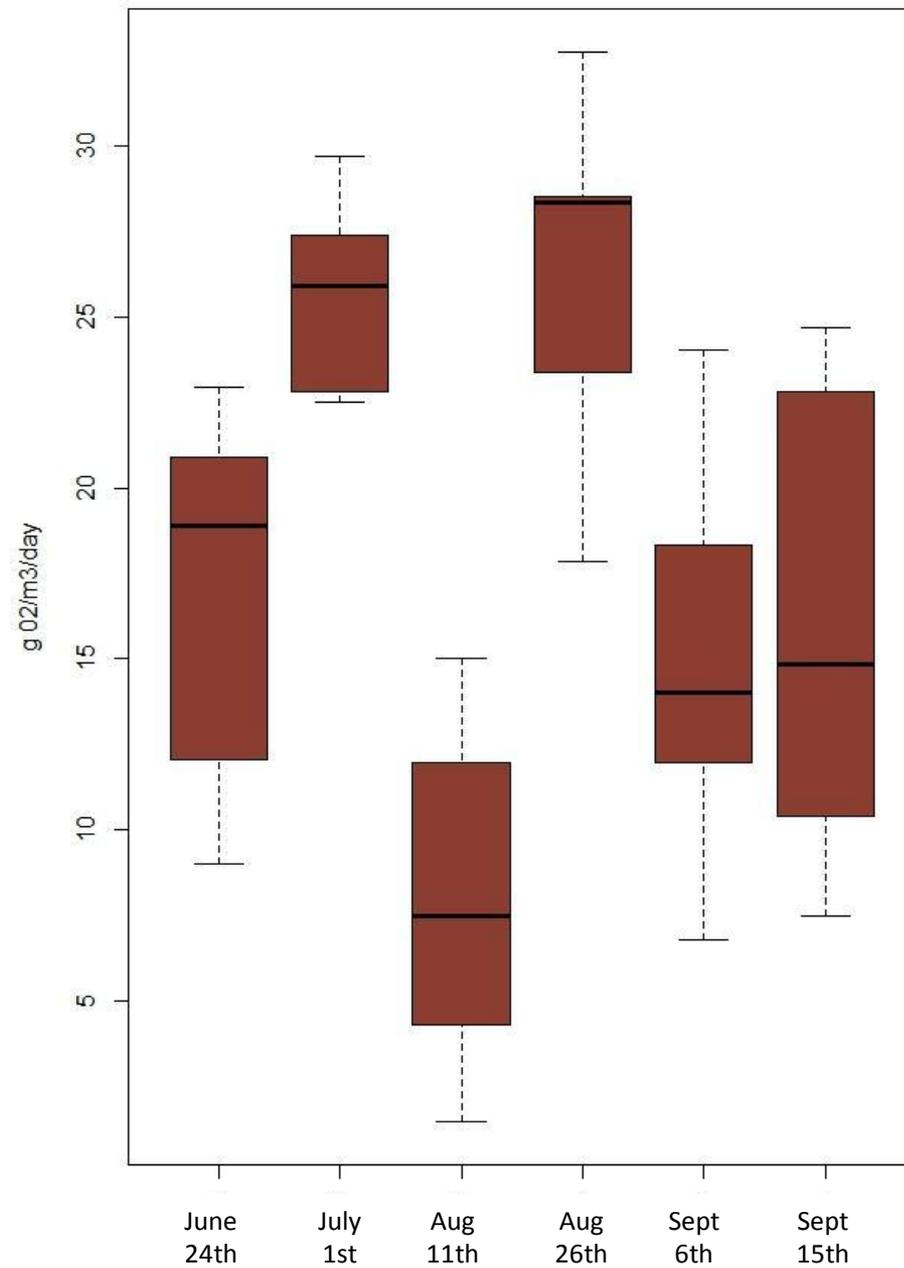

## Respiration

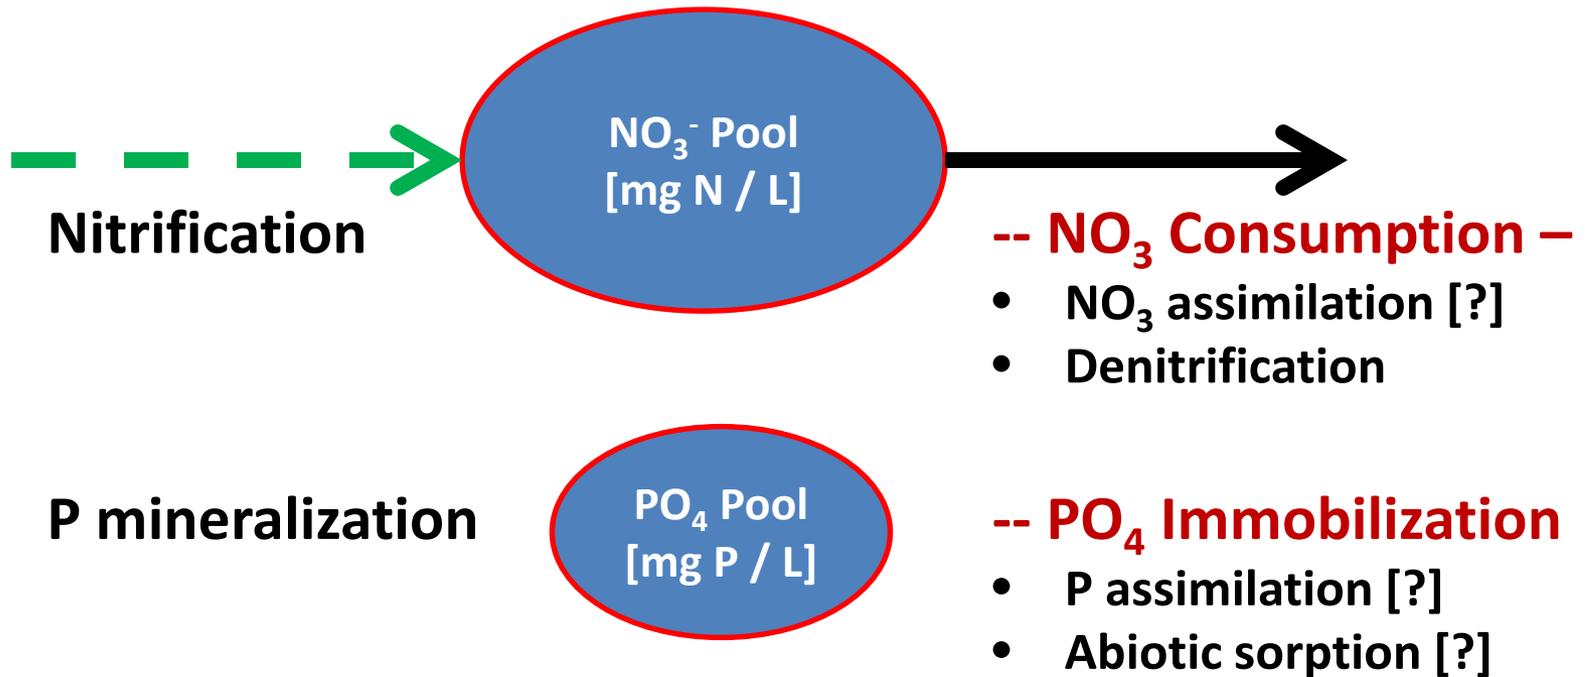

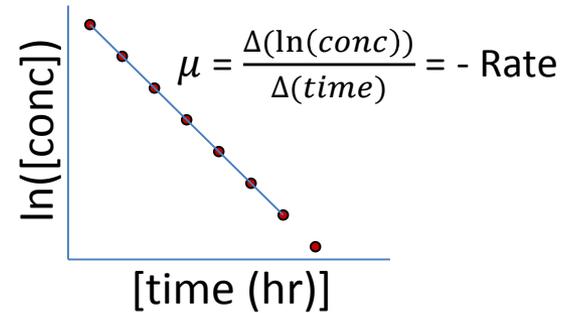

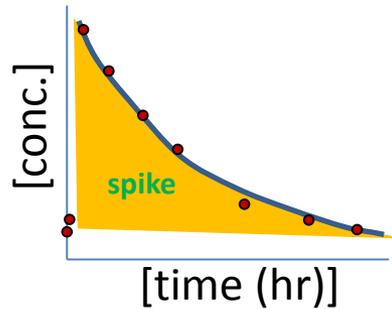

- Oxygen consumption by all organisms during daytime and nighttime
- Rates obtained from differences between daytime and nighttime (no autotrophic O<sub>2</sub> production) DO concentration

Willard Spur Site 4 GPP

Willard Spur Site 4 CR

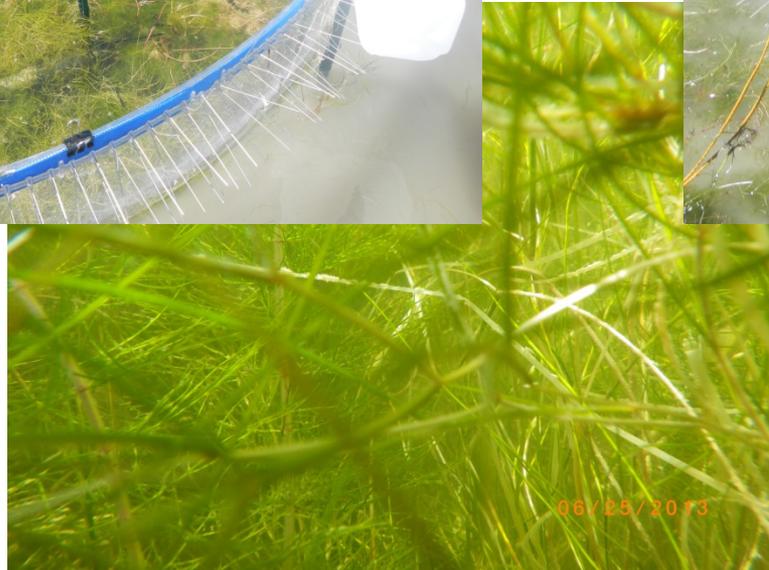

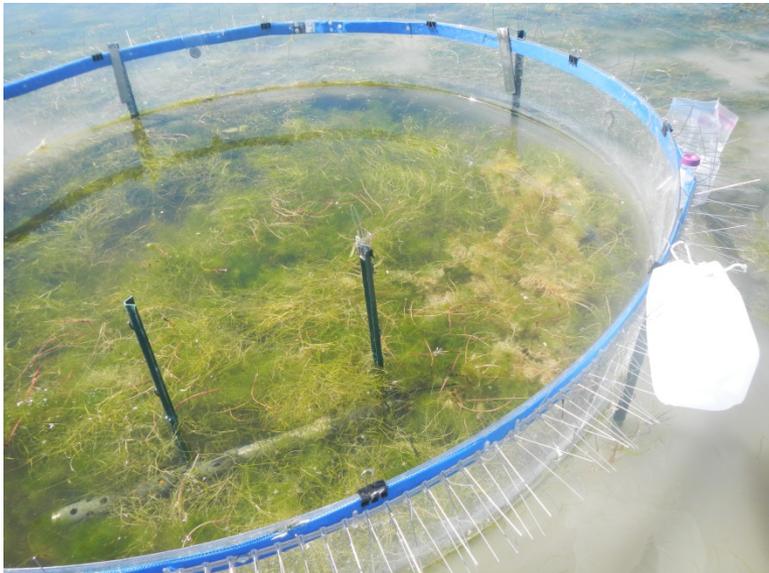

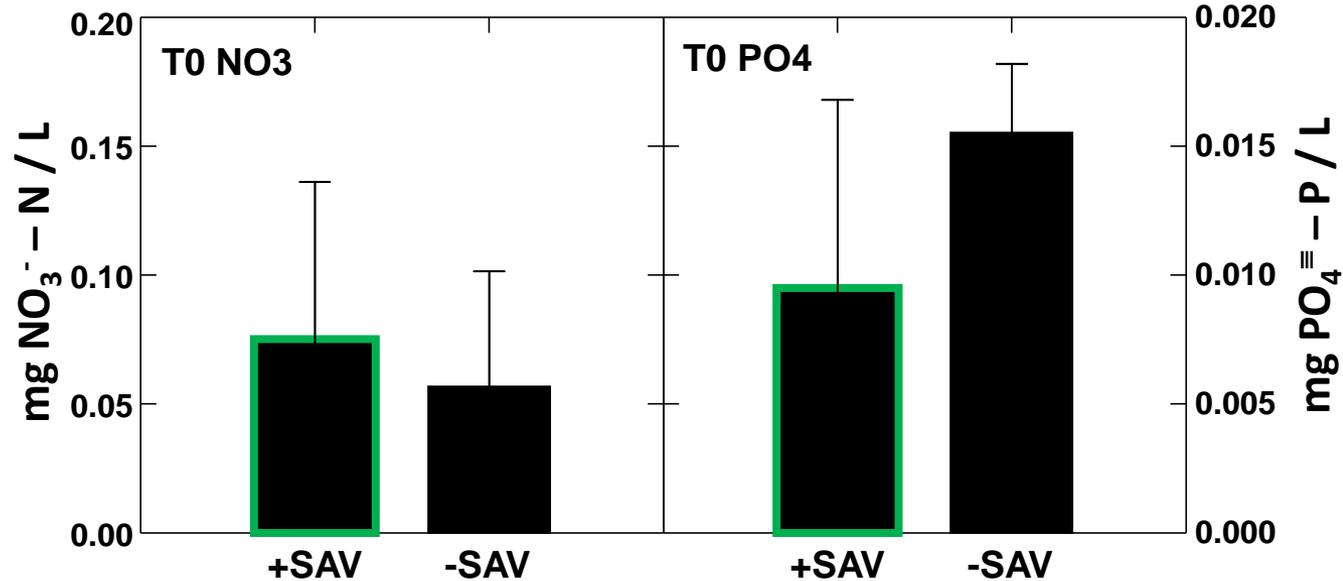

These type of measurements can give us a sense of the magnitude of the kinetics, but *they do not tell us about the fate* of the “removed” or “assimilated” nutrient

## Trip #1 – June 2013

- Installed six (6) 2-m diameter mesocosms 5 days prior to experiment
- Removed SAV from three mesocosms
- Added 0.08 mg NO<sub>3</sub>-N / L and 0.08 mg PO<sub>4</sub>-P / L to each mesocosm
- Collected 50 mL of filtered water over 6 hours (15 min x 8, 30 min x 8)

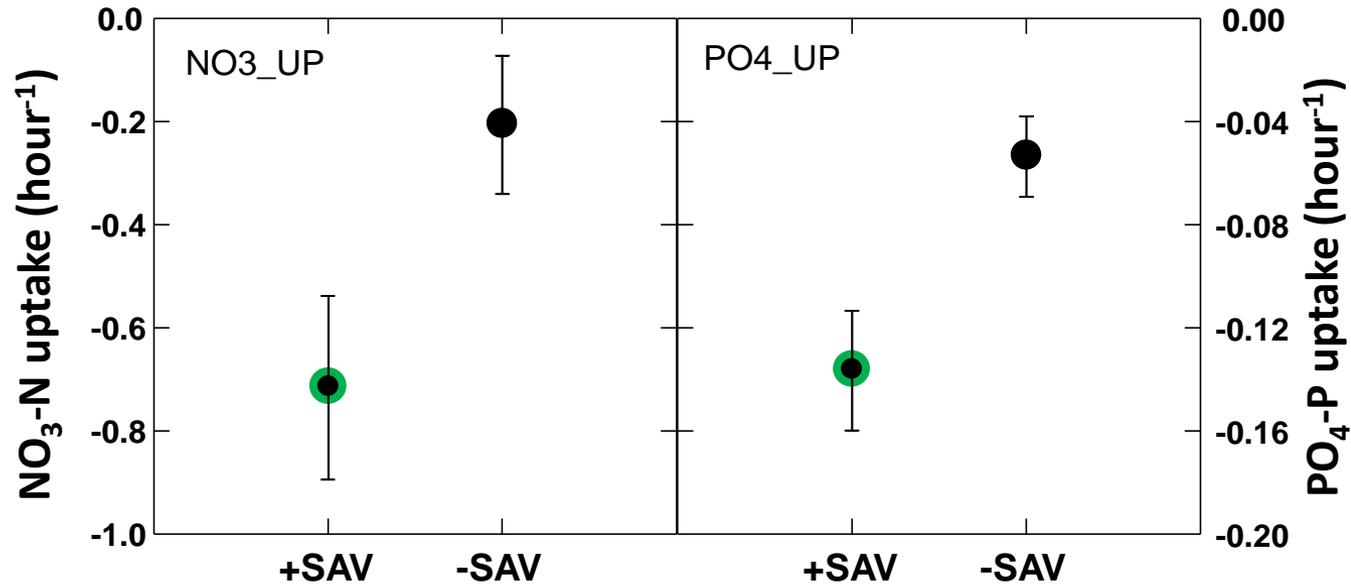

## Trip #1 – June 2013

### Results:

- Initial NO<sub>3</sub> and PO<sub>4</sub> pools were not significantly different among chambers
- Dissolved concentrations: NO<sub>3</sub> > PO<sub>4</sub>
- Nutrient Additions → *Approx. doubling of NO<sub>3</sub> pool*  
PO<sub>4</sub> addition followed NO<sub>3</sub> (1:1)

## Trip #1 – June 2013

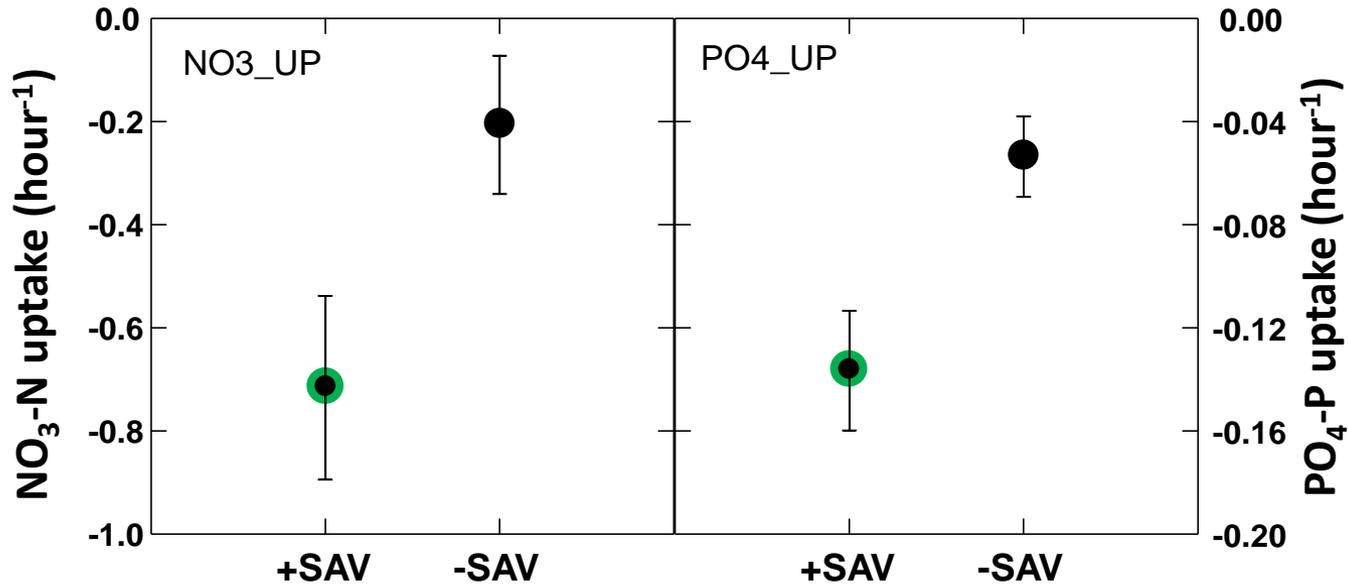

Results:

**Note:**

Results are expressed as Rate Constants (per unit time)

More negative rate-constant  $\rightarrow$  *Faster*

## Trip #1 – June 2013

|              | NO <sub>3</sub> Uptake | PO <sub>4</sub> Uptake |
|--------------|------------------------|------------------------|
| <b>+ SAV</b> | <b>-0.72 ± 0.16</b>    | <b>-0.14 ± 0.02</b>    |
| <b>- SAV</b> | <b>-0.21 ± 0.12</b>    | <b>-0.05 ± 0.01</b>    |

### Results:

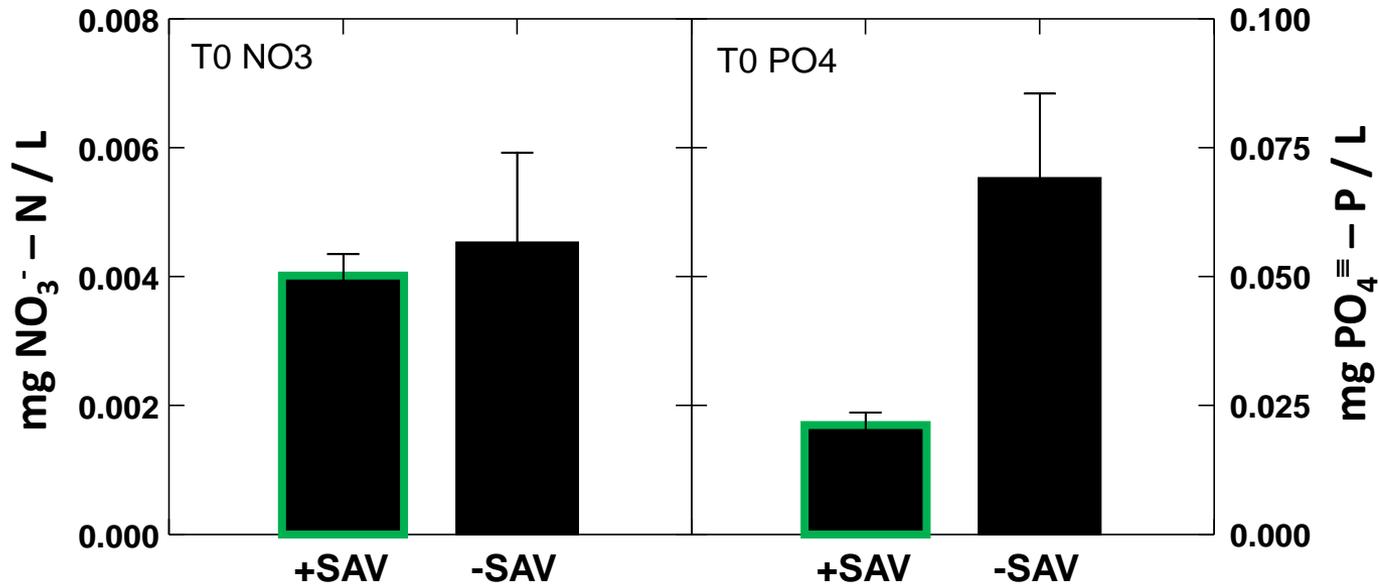

- Uptake rates in plots with SAV faster than without SAV
- NO<sub>3</sub> uptake ≈ 5 times faster than PO<sub>4</sub> uptake

## Trip #2 – August 2013 (Daytime)

- Moved eight (8) mesocosms to new location, 8 days prior to experiment
- -SAV mesocosms were placed in area of low SAV cover, adjacent to +SAV patch
- Added 0.12 mg NO<sub>3</sub>-N / L and 0.12 mg PO<sub>4</sub>-P / L to each mesocosm
- Collected 50 mL of filtered water over 6 hours (15 min x 8, 30 min x 8)

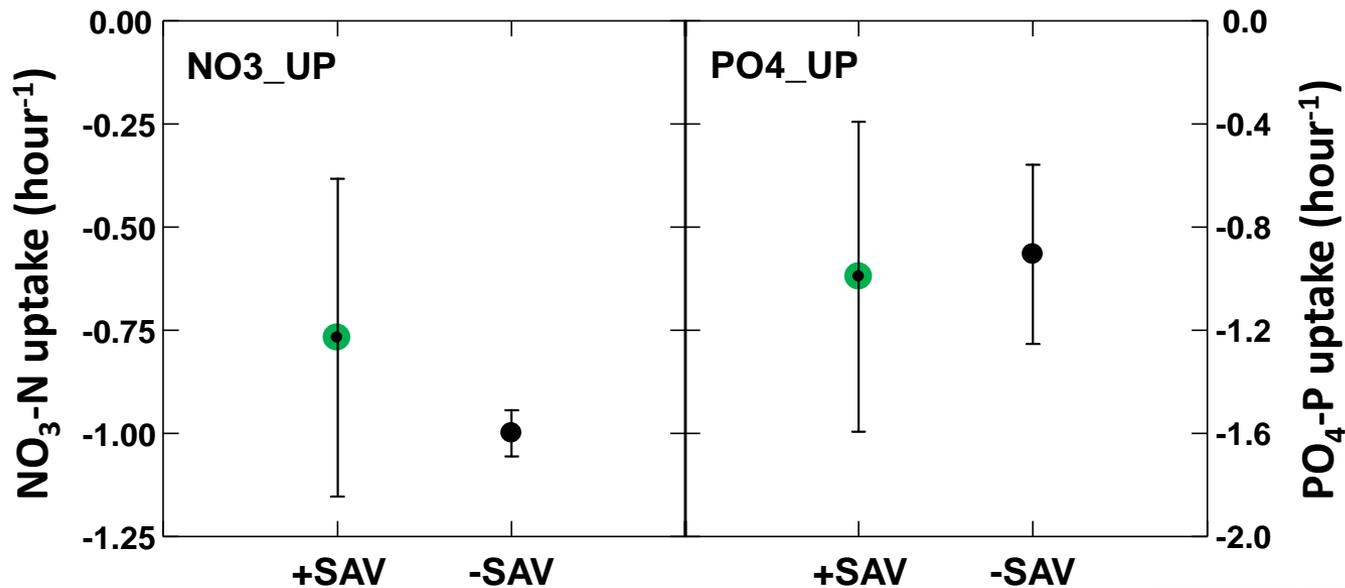

## Trip #2 – August 2013 (Daytime)

### Results:

- No sig. difference in initial (T0) NO<sub>3</sub> pools between treatments
- -SAV had greater dissolved PO<sub>4</sub> concentrations than +SAV (p<0.001)
- PO<sub>4</sub> pools were greater than NO<sub>3</sub> pools

## Trip #2 – August 2013 (Daytime)

|              | NO <sub>3</sub> Uptake | PO <sub>4</sub> Uptake |
|--------------|------------------------|------------------------|
| <b>+ SAV</b> | <b>-0.83 ± 0.23</b>    | <b>-0.99 ± 0.51</b>    |
| <b>- SAV</b> | <b>-1.00 ± 0.05</b>    | <b>-0.90 ± 0.31</b>    |

### Results:

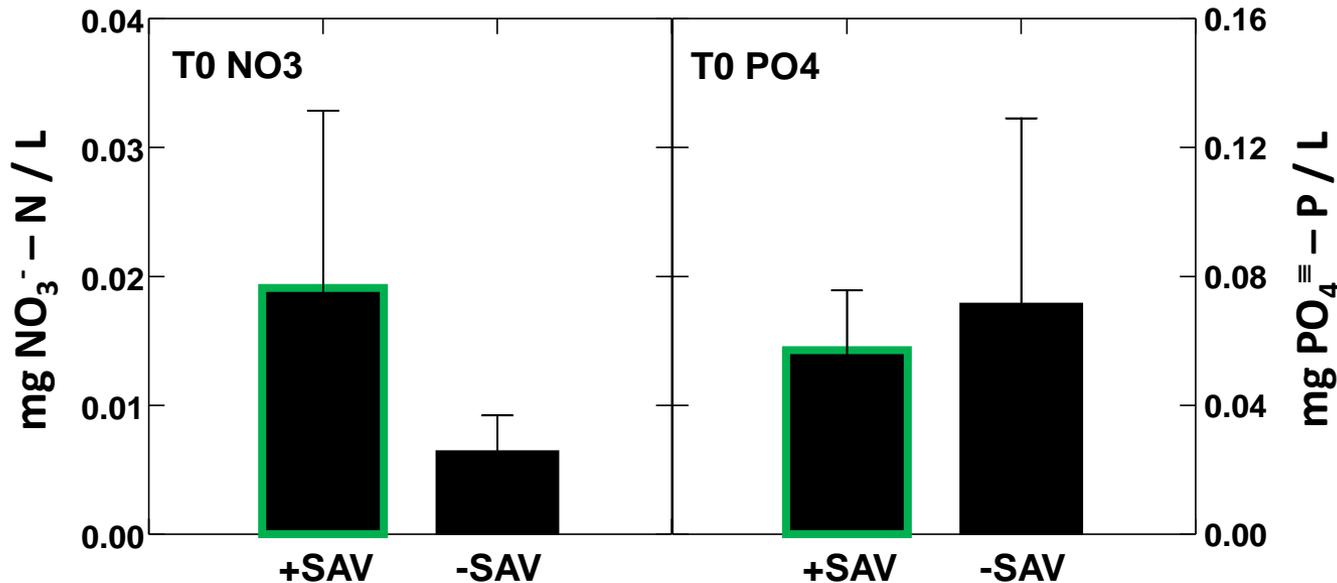

- Uptake rates in plots with SAV not significantly different than –SAV plots
- NO<sub>3</sub> uptake of similar magnitude to PO<sub>4</sub> uptake

Trip #3 – August 2013 (Nighttime)

08/23/2013

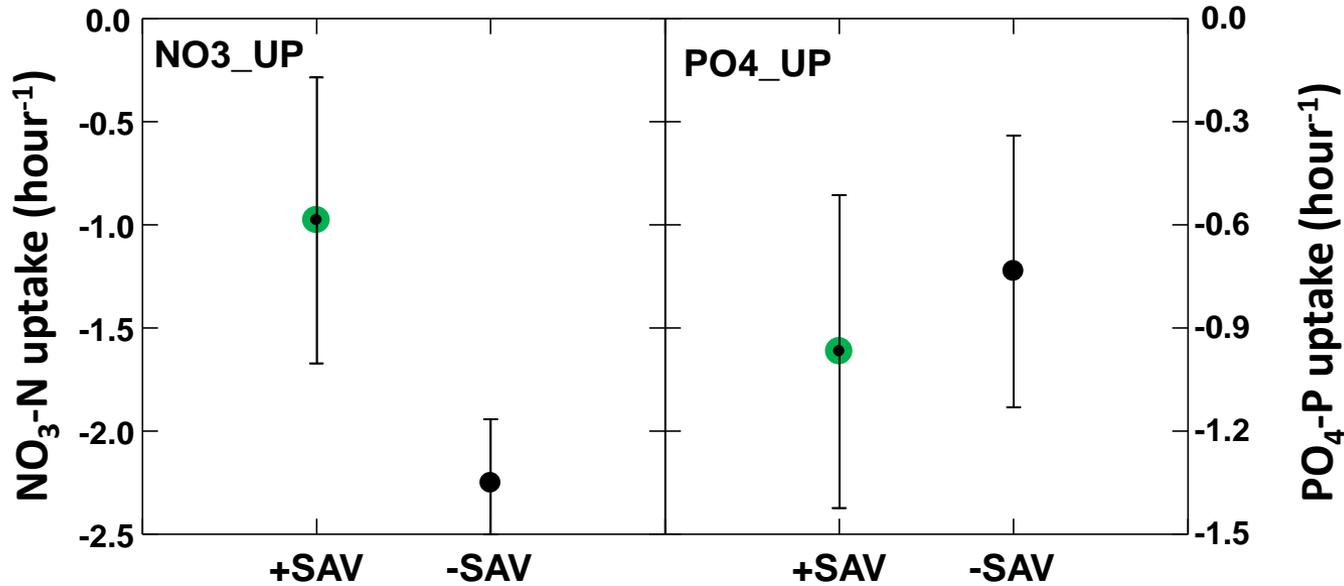

### Trip #3 – August 2013 (Nighttime)

#### Results:

- Plots w/ SAV had slightly greater initial NO<sub>3</sub> concentrations than –SAV plots (p=0.054), while PO<sub>4</sub> concentrations did not differ
- Initial concentrations were generally higher at night than the previous (3 days prior) sampling during the day
- PO<sub>4</sub> concentrations about 6 to 8 times the size of NO<sub>3</sub> pools

### Trip #3 – August 2013 (Nighttime)

|              | NO <sub>3</sub> Uptake | PO <sub>4</sub> Uptake |
|--------------|------------------------|------------------------|
| <b>+ SAV</b> | <b>-0.98 ± 0.62</b>    | <b>-0.97 ± 0.41</b>    |
| <b>- SAV</b> | <b>-2.25 ± 0.28</b>    | <b>-0.74 ± 0.36</b>    |

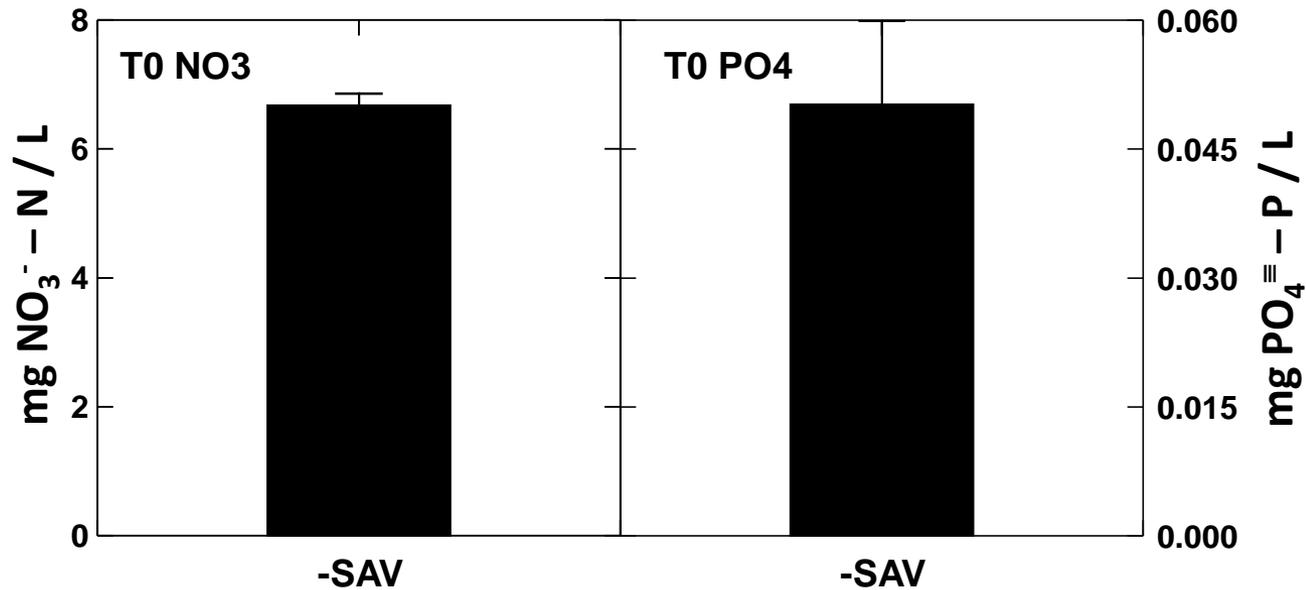

#### Results:

- *Interestingly*, -SAV plots had greater NO<sub>3</sub> uptake than +SAV plots
- NO<sub>3</sub> uptake in -SAV plots was very rapid
- In +SAV plots, NO<sub>3</sub> uptake similar to PO<sub>4</sub> uptake
- For -SAV plots, NO<sub>3</sub> uptake >> PO<sub>3</sub> uptake

# Trip #4 – September 2013 \*\* Tailrace \*\*

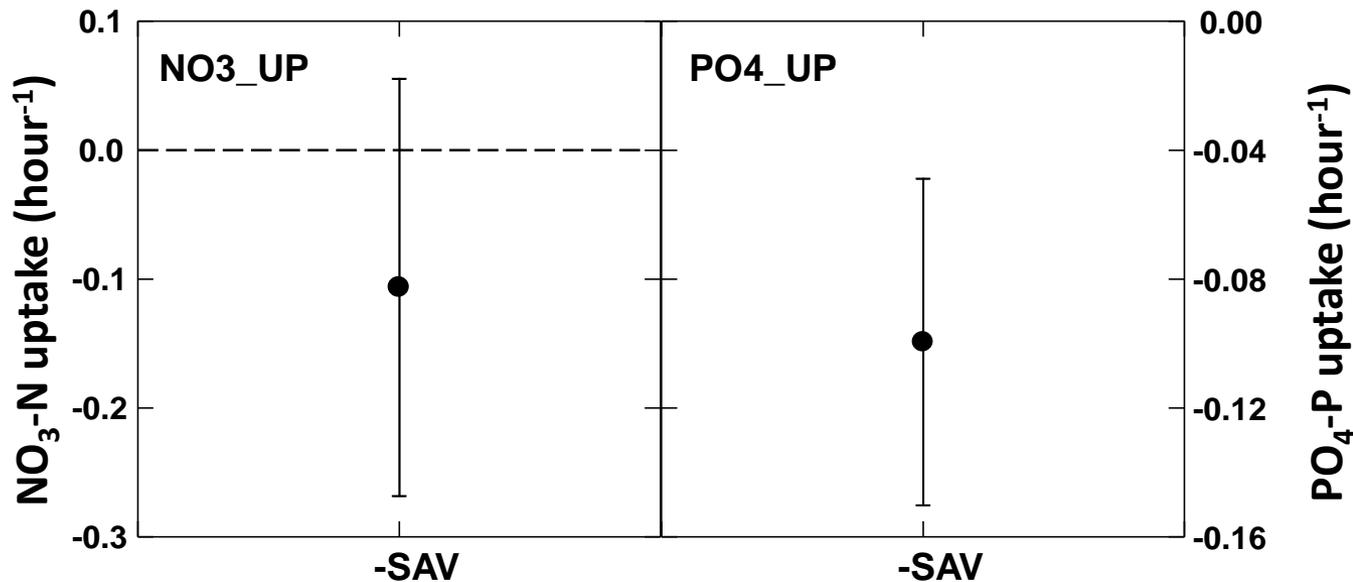

## Trip #4 – September 2013 \*\* Tailrace \*\*

### Results:

- No SAV were observed in the Tailrace
- Initial NO<sub>3</sub> pools were very, very high. Approx. 2 orders of magnitude greater than previous measurements in open water areas of Willard Spur
- Initial PO<sub>4</sub> concentrations were similar to other late-summer pools
- Because of large NO<sub>3</sub> pools – the NO<sub>3</sub> spike was quite small (in a relative sense)

## Trip #4 – September 2013 \*\* Tailrace \*\*

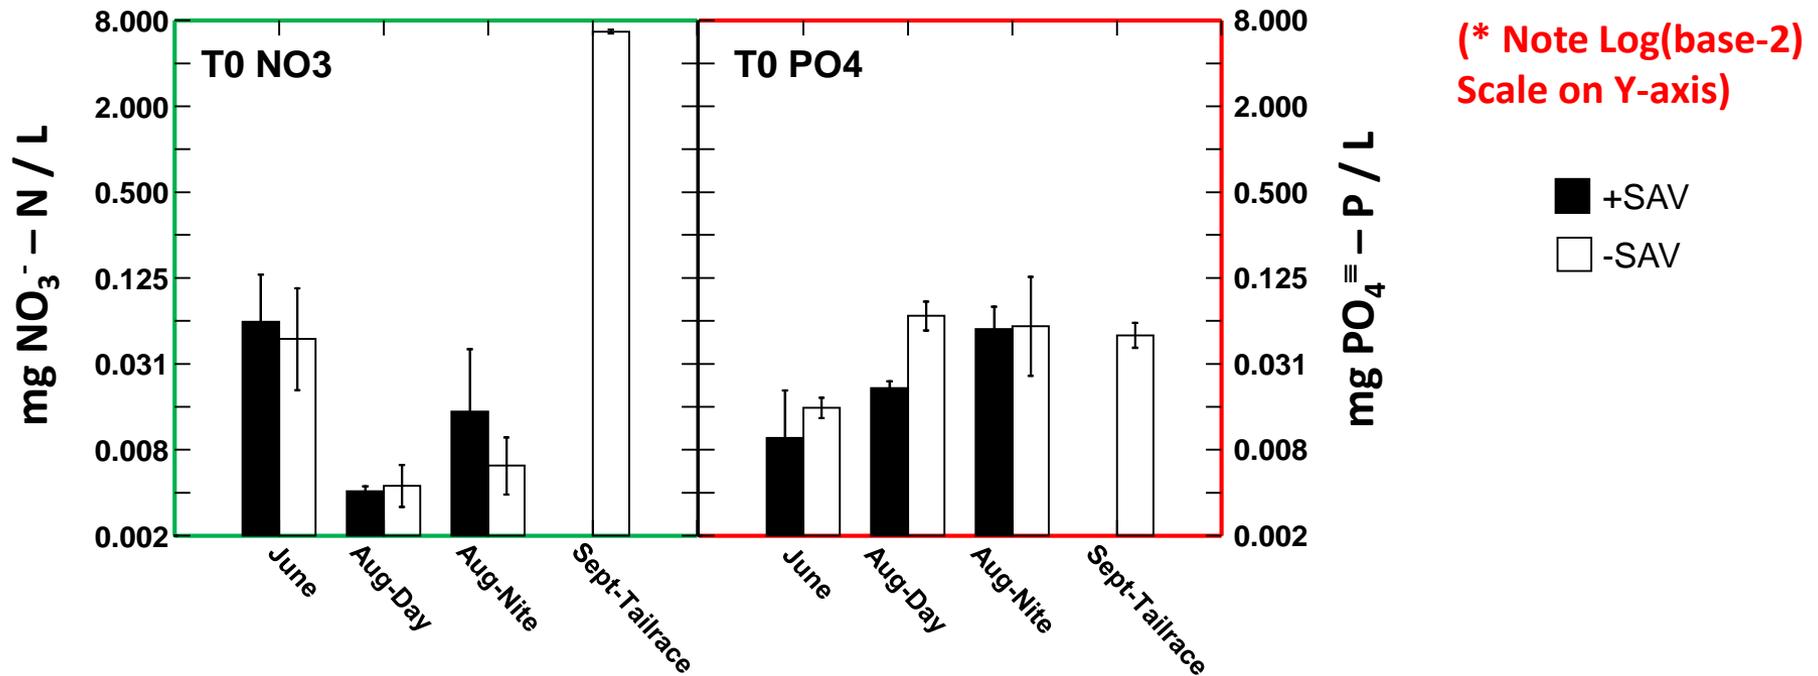

|              | NO <sub>3</sub> Uptake | PO <sub>4</sub> Uptake |
|--------------|------------------------|------------------------|
| <b>- SAV</b> | <b>-0.11 ± 0.15</b>    | <b>-0.10 ± 0.05</b>    |

### Results:

- Uptake rate constants similar between NO<sub>3</sub> and PO<sub>4</sub>
- Considerable variability in NO<sub>3</sub> uptake; two measurements have  $r^2 < 0.50$
- Use of Br<sup>-</sup> tracer may help clear up methodological issues

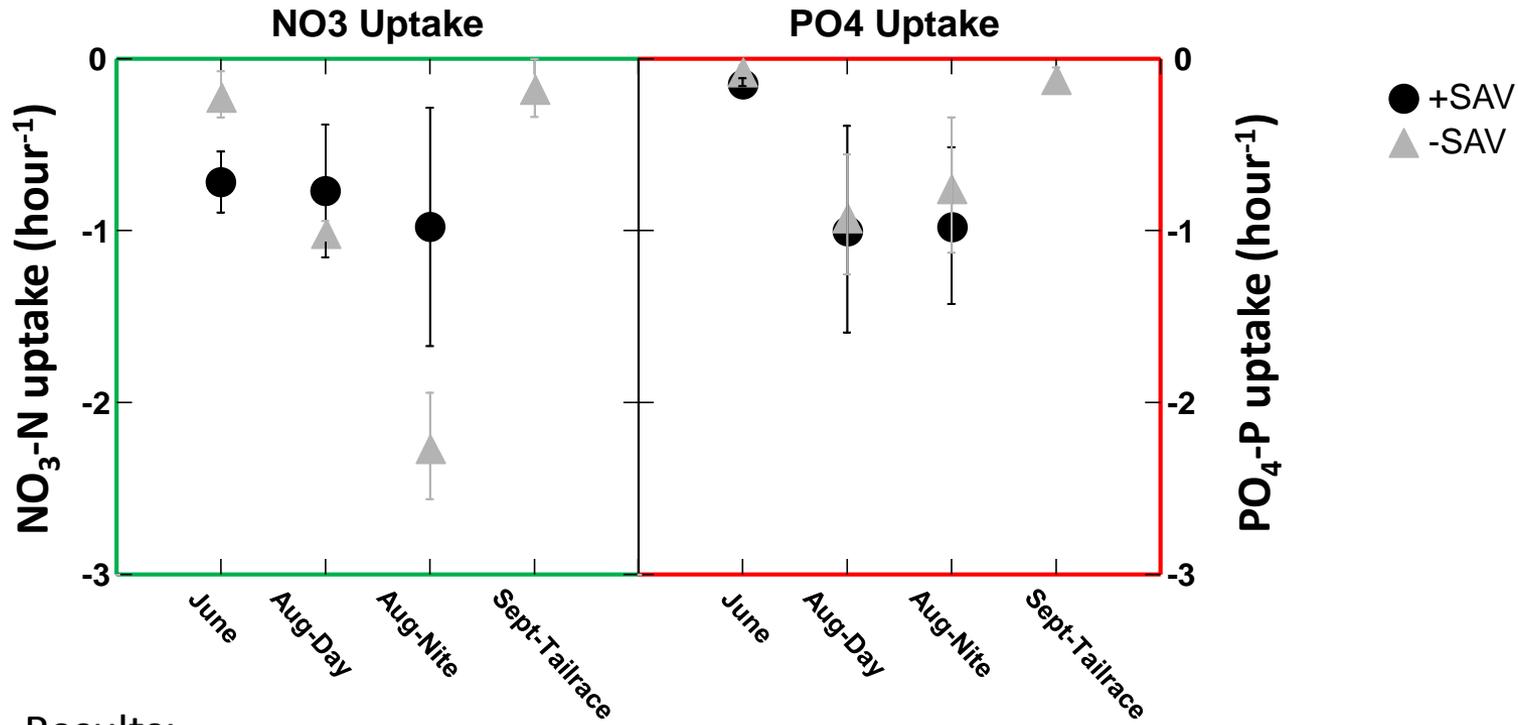

## All Sampling Trips Combined

### Results:

- NO<sub>3</sub> concentrations tended to decrease over time within the Spur, but were much higher in the Tailrace
- NO<sub>3</sub> concentrations were slightly higher at night than during the day
- PO<sub>4</sub> concentrations increased from June through August

## All Sampling Trips Combined

### Results:

- NO<sub>3</sub> Uptake with SAV: Generally similar over time, but variability increases over time
- NO<sub>3</sub> Uptake w/o SAV: Rate constants increase in magnitude from June to August
- PO<sub>4</sub> Uptake – Slow in June and Sept (tailrace), faster in August
- PO<sub>4</sub> – less sensitive to SAV presence than NO<sub>3</sub>

## Scaling of Rate Constants...

$$Rate = \frac{(-k) \cdot Vol \cdot (T_0 Pool)}{Area} = \frac{1}{hour} \cdot \frac{m^3}{m^2} \cdot \frac{g(X)}{m^3} = \frac{g(X)}{m^2 \cdot hour}$$

## NO<sub>3</sub> Uptake Rates

Values are Estimate of Nutrient Load divided by Uptake Rate, by Trip and Vegetation Type. Upper values are for Low Water conditions, Lower values for High Water Conditions. Trip 4 shown only for Tailrace area

What does this mean in the  
context of minimizing the  
potential risk of the  
discharge?

# High Water vs. Low Water Years

## TN

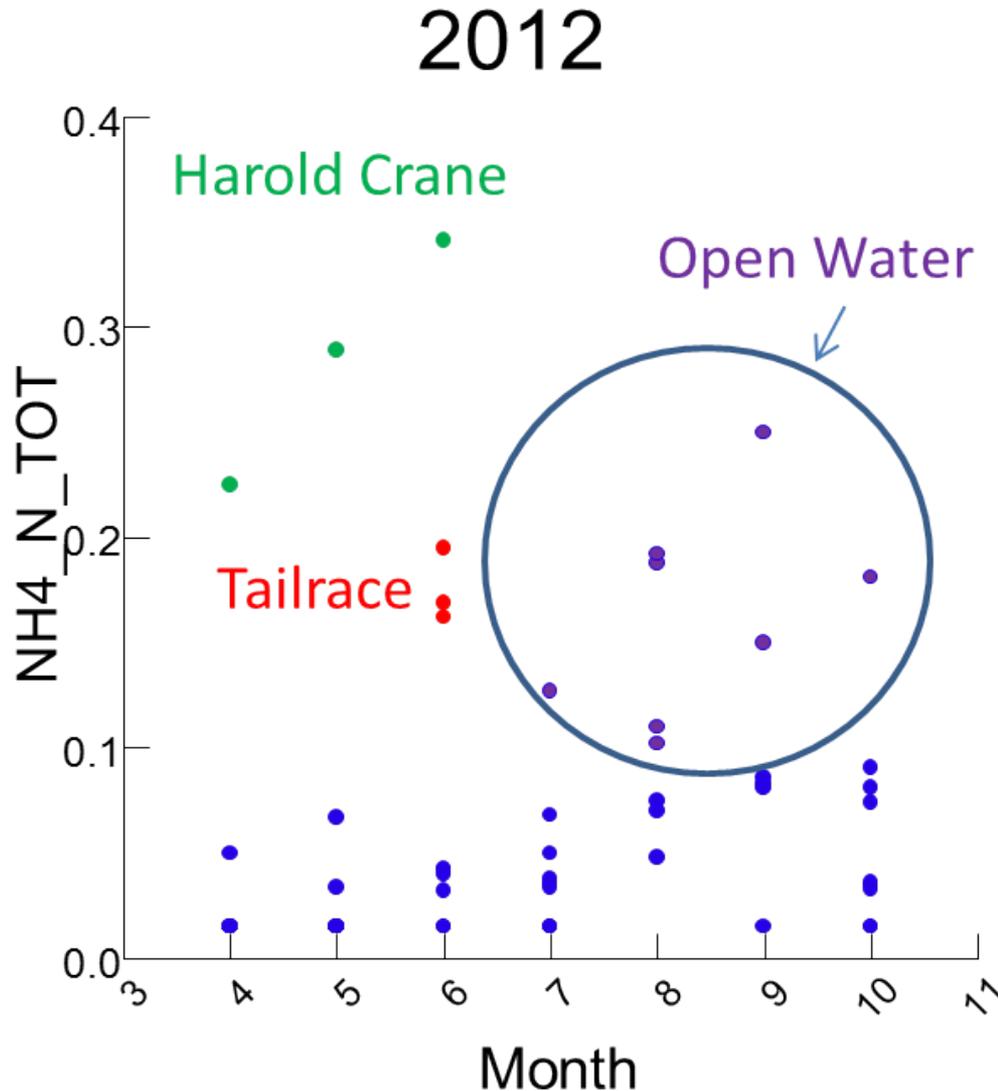

- Increased over time in 2012, not 2011
  - Flushing?
- Highest TN concentrations in late summer
- 90%ile:
  - 2011 = 0.88 mg N/L
  - 2012 = 3.18 mg N/L

## TP

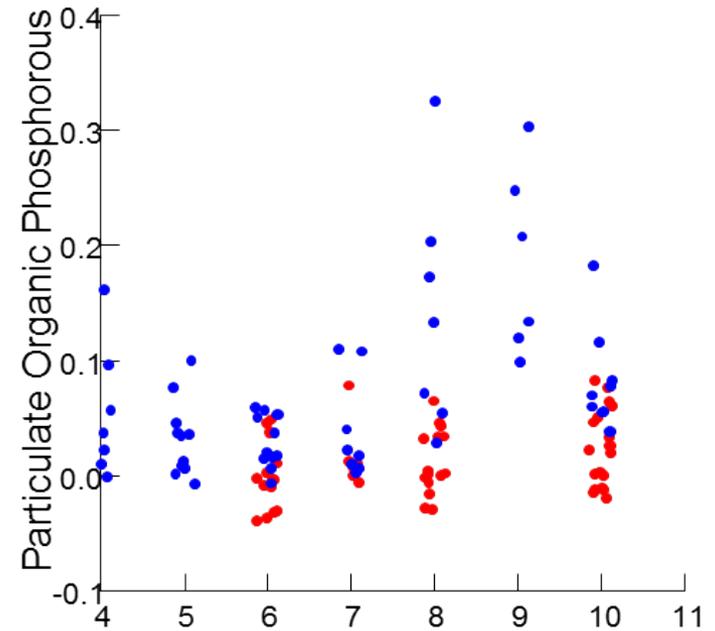

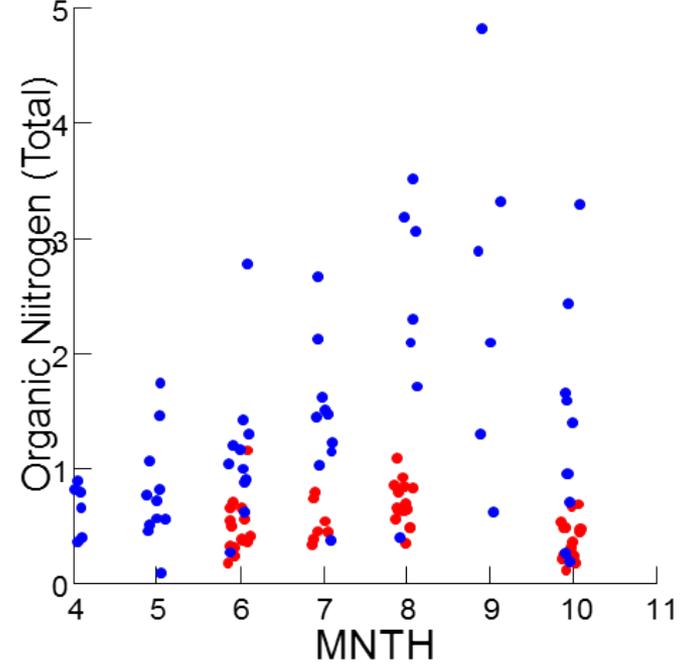

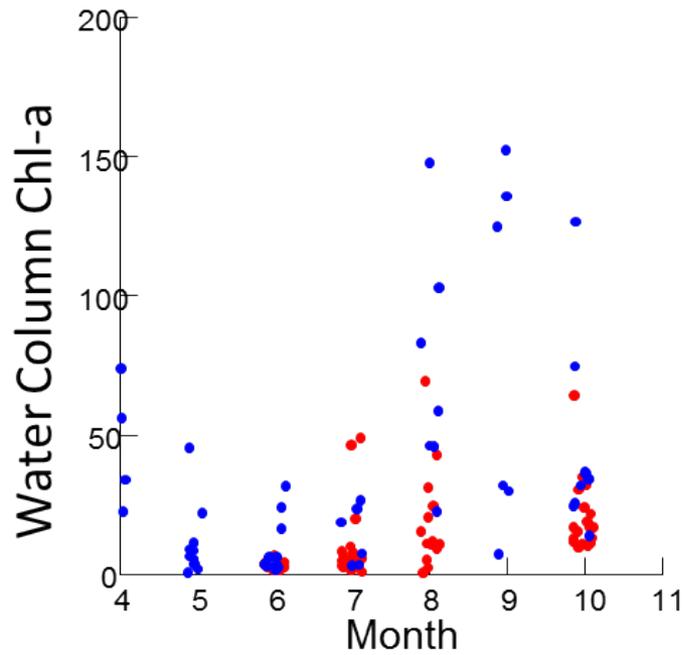

- Increased over time in 2012, not 2011
- 90%ile:
  - 2011 = 0.098 mg P/L
  - 2012 = 0.333 mg P/L

# Internal Cycling: Mineralization

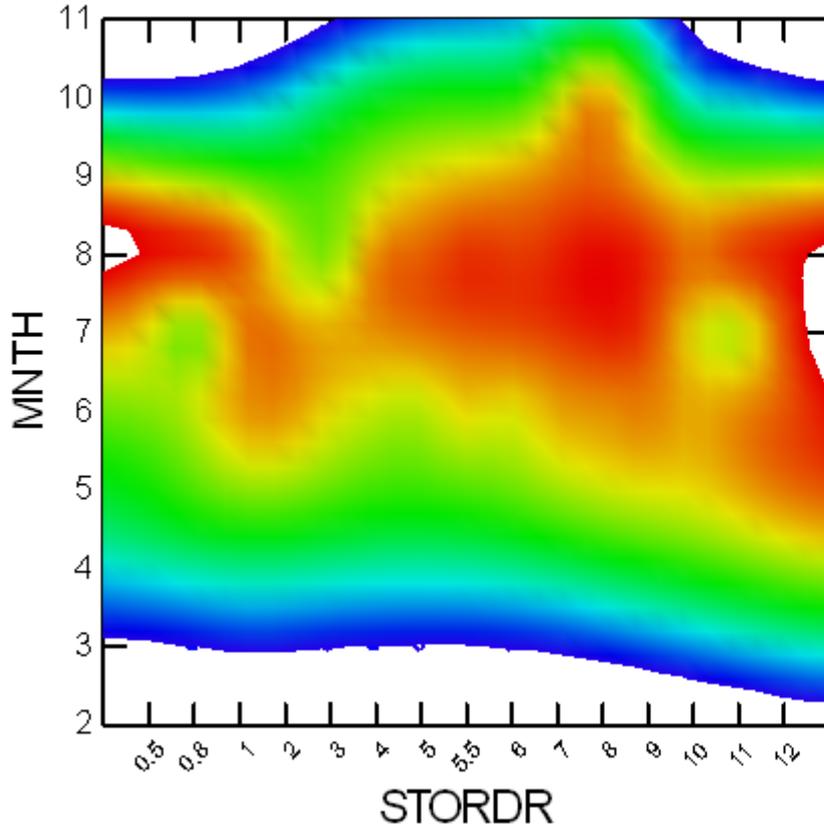

- DO Data in 2012 showed fairly long periods of anoxic conditions (<1 mg/l)
- Evidence of mineralization: ON to NH<sub>4</sub>
- ***Reflects importance of internal nutrient cycling:*** higher values, in more places after the Spur is mostly isolated.

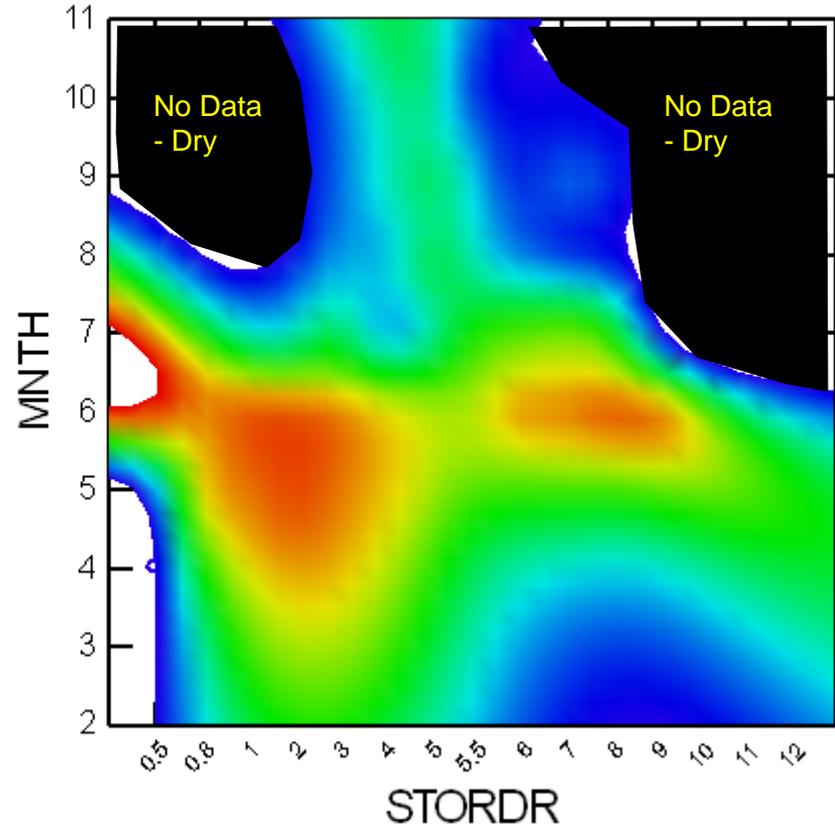

# Organic N & P

2011

2012

**Red = High Cover**

**Blue = Low Cover**

# The Relative Threat of Nutrient Inputs Depends on the Timing

- Springtime loads are appreciable, but transient
  - Export or uptake
  - Assimilative capacity of the spur is high
- Summertime loads, from the organic nutrient pools are most important
- During periods where the spur is isolated, the potential risk of the plant is greatest

# Quantifying Internal Cycling

## Next Steps

### **Internal Cycling**

- Nutrient spiraling within the tailrace
- Estimate the mass of the organic nutrient pool associated with macrophytes
- Quantify the potential load from these sources in comparison with the discharge

### **Ecosystem Metabolism**

- Link rates to processes

### **Others Summaries of Background Monitoring**

- Many ways to do this, what would be most useful in the context of potential panel recommendations?

# High Ecological Resilience: How to maintain this characteristic?
